

Unity 1

1. ProcessingHCI

A challenge when dev teams work with quality attributes that require a large effort to verify and assess usually are left out or misunderstood of the process development. The mainstream of agile methods sometimes increases the hurdles rather to improve the process because teams miscalculate efforts. It is recognized an UX Lean as technique to match the agile process. Based on the experience of your team:

Key points of the Lean UX technique

Considering the key points of the lean UX Technique and based on the experience of your team's project, reflect on the process' team, could be considered lean?

How much effort in terms of roles, activities, task would require your team's process to be considered lean? Is it worth in terms of benefits or cost?

Note: Use the following link as initial resource.

<https://www.interaction-design.org/literature/article/a-simple-introduction-to-lean-ux>

Our process can't be considered Lean UX because, according to the source consulted, this technique requires a high level of constant collaboration among all team members, including designers, developers, and other key roles. Although we did work together on our team, there was no such close integration or continuous validation dynamic, which is essential in Lean UX. What caught my attention most was the focus on obtaining feedback as early as possible, as this allows us to adjust the product quickly and make informed decisions without waiting for final phases. For our process to be considered Lean, we would have to redefine roles, incorporate early validation activities, increase interaction with real users, and prioritize continuous learning, in addition to having greater collaboration. This change would entail considerable effort, but I believe it is worth it if the goal is to build more user-centered solutions and reduce the risk of costly errors in the long term.

2. AI Tools

AI tools are on fashion. Developers are exploring the potential of tools such as chat GPT to generate automatically apps. There are many examples of code produce by AI tools. Research and select one tool, explore and try some examples to produce UI that includes specific features related with usability attributes. Based on your research and experience explain the real potential of the AI tools and the constrains. Provide some arguments related the following points:

What's the quality of the UI you could produce?

How was your experience producing UI with an AI tool? Is it easy to use the AI tool?

Considering the final result of the UI, to how extend it include the usability attribute?

Will the UX role change significantly with the development of AI tools? How?

<https://youtu.be/uwSY9XqQGxw>

The AI tool that I chose for this activity was **Firestore Studio**, with which I generated screens such as the soft skills catalog, lessons, and daily challenges, including specific features related to usability attributes such as clarity, consistency, and feedback. **The quality of the generated interface is quite good for prototyping purposes**, as the visual elements are clean and understandable, although in some cases the tool produces generic components if not given precise instructions. **The experience was positive**, as it is easy to use and allows for the rapid creation of interfaces that previously could have taken months. However, it is essential to be very specific when requesting what you want, as it does not always correctly interpret what we want to prototype. **Although I did not conduct formal usability tests, I can empirically say that the interface I generated in Firestore Studio was understandable and easy to navigate. The true potential of these tools is their ability to accelerate interface creation and facilitate experimentation.** However, their real scope is currently limited to rapid prototyping, as they do not yet automatically incorporate deeper aspects. In other words, I highly doubt that they can completely replace those in charge of this role. However, I believe that they will complement them and make them more efficient and faster.
